    d::add_edge(3,d::snk,1);
    d::add_edge(4,d::snk,1);
    cout<<d::dinic()<<endl; // SHOULD OUTPUT 4
    d::recover();
}
```

Flow with demands

Finding an arbitrary flow

- Assume a network with $[L;R]$ on edges (some may have $L=0$), let's call it old network.
- Create a New Source and New Sink (this will be the src and snk for Dinic).
- Modelling network:
  1. Every edge from the old network will have cost $R-L$
  2. Add an edge from New Source to every vertex v with cost:
     - $S(L)$ for every (u,v). (sum all L that LEAVES v)
  3. Add an edge from every vertex v to New Sink with cost:
     - $S(L)$ for every (v,w). (sum all L that ARRIVES v)
  4. Add an edge from Old Source to Old Sink with cost INF (circulation problem)
- The Network will be valid if and only if the flow saturates the network (max flow == $S(L)$)

Finding Min Flow

- To find min flow that satisfies just do a binary search in the (Old Sink -> Old Source) edge
- The cost of this edge represents all the flow from old network
- Min flow = $S(L)$ that arrives in Old Sink + flow that leaves (Old Sink -> Old Source)

Kosaraju's algorithm

```
/*****************************************************************************
* KOSARAJU'S ALGORITHM (GET EVERY STRONGLY CONNECTED COMPONENTS (SCC))      *
* Description: Given a directed graph, the algorithm generates a list of every    *
* strongly connected components. A SCC is a set of points in which you can reach  *
* every point regardless of where you start from. For instance, cycles can be     *
*   a   SCC   themselves   or   part   of   a   greater   SCC.
*
```

```
* This algorithm starts with a DFS and generates an array called "ord" which      *
* stores vertices according to the finish times (i.e. when it reaches "return").  *
* Then, it makes a reversed DFS according to "ord" list. The set of points        *
*   visited   by   the   reversed   DFS   defines   a   new   SCC.                  *
*                                                                                 *
* One of the uses of getting all SCC is that you can generate a new DAG (Directed *
* Acyclic Graph), easier to work with, in which each SCC being a "supernode" of   *
* the DAG.                                                                        *
* Time complexity: O(V+E)                                                         *
*   Notation:   adj[i]:          adjacency   list   for   node   i                *
*                                                                                 *
*                  adjt[i]:   reversed  adjacency  list  for  node  i             *
*                                                                                 *
*            ord:       array of vertices according to their finish time         *
*         ordn:    ord counter                                                   *
*        scc[i]:  supernode assigned to i                                         *
*                  scc_cnt:   amount  of  supernodes  in  the  graph              *
*                                                                                 *
