Sum formulas

$$(a+b)^2 = a^2 + 2ab + b^2$$

$$\sum_{k=1}^n k = \frac{n(n+1)}{2}$$

$$\sum_{k=1}^n k^2 = \frac{n(n+1)(2n+1)}{6}$$

$$\sum_{k=1}^n k^3 = \frac{n^2(n+1)^2}{4}$$

$$\sum_{k=1}^n k^4 = \frac{n(n+1)(2n+1)(3n^2 + 3n - 1)}{30}$$

Flow with demands

Finding an arbitrary flow

- Assume a network with [L; R] on edges (some may have L = 0), let's call it old network.
- Create a New Source and New Sink (this will be the src and snk for Dinic).
- Modelling network:
- 1. Every edge from the old network will have cost R-L
- 2. Add an edge from New Source to every vertex v with cost:
 - S(L) for every (u, v). (sum all L that LEAVES v)
- 3. Add an edge from every vertex v to New Sink with cost:
 - S(L) for every (v, w). (sum all L that ARRIVES v)
- Add an edge from Old Source to Old Sink with cost INF (circulation problem)
- The Network will be valid if and only if the flow saturates the network (max flow == S(L))

Finding Min Flow

- To find min flow that satisfies just do a binary search in the (Old Sink
 Old Source) edge
- The cost of this edge represents all the flow from old network
- Min flow = S(L) that arrives in Old Sink + flow that leaves (Old Sink -> Old Source)

Kosaraju's algorithm

```
* KOSARAJU'S ALGORITHM (GET EVERY STRONGLY CONNECTED COMPONENTS (SCC)) *

* Description: Given a directed graph, the algorithm generates a list of every *

* strongly connected components. A SCC is a set of points in which you can reach *

* every point regardless of where you start from. For instance, cycles can be *

* a SCC themselves or part of a greater SCC.
```

```
scc[u] = scc\_cnt, vis[u] = 0;
* This algorithm starts with a DFS and generates an array called
                                                                      for (auto v : adj[u]) if(vis[v] and u != par[v]) dfst(v);
                                                                                                                                     void kmp() {
                                                                                                                                      for (int i = 0, j = 0; i < n;) {
* stores vertices according to the finish times (i.e. when it reaches
                                                                                                                                        while (j \ge 0 \text{ and } s[i] != p[j]) j=b[j];
                                                                    // add edge: u -> v
                                                                                                                                        i++, j++;
* Then, it makes a reversed DFS according to "ord" list. The set of
                                                                    void add edge(int u, int v){
                                                                                                                                        if (j == m) {
                                                                      adj[u].push back(v);
                                                                                                                                         // match position i-j
* visited by the reversed DFS defines a new SCC.
                                                                      adj[v].push_back(u);
